## Exercise 4

Let's define  $X$  as the number of heads observed in 20 tosses. From the exercise, we know that  $X \sim \text{Binomial}(n = 20, p)$ .

### Part a

We recall the Neyman-Pearson lemma presented on page 5 (Hypothesis testing, weeks 8 and 9).

**Lemma. The Neyman-Pearson lemma:** Let  $H_0$  and  $H_a$  be simple hypothesis and let  $f_0$  and  $f_a$  denote the joint pdf or pmf under  $H_0$  and  $H_a$  respectively. Then the test that rejects for small values of

$$T(\underline{X}) = \frac{f_0(\underline{x})}{f_a(\underline{x})}$$

is most powerful for testing  $H_0$  against  $H_a$ .

Note  $T(\underline{X})$  in the above is simply the ratio of the likelihoods under  $H_0$  and  $H_a$ .

In our case, we have that

$$H_0 : p = p_0 \text{ versus } H_a : p = p_a, \quad (1)$$

with  $p_a > p_0$ . From the Neyman-Pearson lemma, we have that the most powerful test for testing  $H_0$  against  $H_a$  is given by

$$T(\underline{X}) = \frac{f_0(\underline{x})}{f_a(\underline{x})}, \quad (2)$$

$$= \frac{\prod_{i=1}^K \binom{n}{x_i} p_0^{x_i} (1-p_0)^{n-x_i}}{\prod_{i=1}^K \binom{n}{x_i} p_a^{x_i} (1-p_a)^{n-x_i}}, \quad (3)$$

$$= \left(\frac{p_0}{p_a}\right)^{\sum_{i=1}^K x_i} \left(\frac{1-p_0}{1-p_a}\right)^{Kn - \sum_{i=1}^K x_i}. \quad (4)$$

We reject  $H_0$  when  $T(\underline{X})$  is small (i.e., when  $\sum_{i=1}^K x_i$  is large).

## part b

We know that  $\alpha = 0.05 \Rightarrow z_{(0.05)} = 1.64$ ,  $p_0 = 0.5$  (considering a fair coin) and  $n = 20$ .

Here, the size of the rejection region is given by  $\{X : X \geq C | H_0\}$ , where  $P(X \geq C | H_0) = 0.05$ . In addition, as we're supposed to use the Normal approximation, we know that

$$X \sim N(np_0, np_0(1-p_0)), \text{ under } H_0. \quad (5)$$

How do we know that? Let's have a look at page 2 (weeks 8 and 9) and [https://en.wikipedia.org/wiki/Binomial\\_distribution#Normal\\_approximation](https://en.wikipedia.org/wiki/Binomial_distribution#Normal_approximation). Hence,

$$P(X \geq C | H_0) \approx P\left(\frac{X - \mathbb{E}(X)}{\sqrt{\mathbb{V}(X)}} \geq \frac{C - \mathbb{E}(X)}{\sqrt{\mathbb{V}(X)}}\right) = 0.05 \quad (6)$$

$$= P\left(Z \geq \frac{C - \mathbb{E}(X)}{\sqrt{\mathbb{V}(X)}}\right) = 0.05 \quad (7)$$

$$= P\left(Z \geq \frac{C - np_0}{np_0(1-p_0)}\right) = 0.05 \quad (8)$$

$$= P(Z \geq 1.64) = 0.05. \quad (9)$$

If we solve

$$\frac{C - 20 \times 0.5}{20 \times 0.5(1-0.5)} = 1.64 \quad (10)$$

we'll find that  $C = 13.67$ . That is, if  $X > 13.67$ , we have evidence to reject  $H_0$ . Given that  $X = 14$ , we reject  $H_0$  (i.e, we can say that the coin isn't fair).

### part c

To calculate the power of the test, we know that  $p_a = 0.7$ . Again, let's have a look at page 2 (weeks 8 and 9). Here, the power of the test is given by  $\{X : X \geq C|H_a\}$ , where  $P(X \geq C|H_a) = ?$ .

$$P(X \geq C|H_1) \approx P\left(Z \geq \frac{C - np_a}{np_a(1 - p_a)}\right) \quad (11)$$

$$= P\left(Z \geq \frac{13.67 - 20 \times 0.7}{20 \times 0.7(1 - 0.7)}\right) \quad (12)$$

$$= P(Z \geq -0.163) = 0.564, \quad (13)$$

which can be obtained in R via `1 - pnorm(-0.163) = 0.564`.

## Exercise 3

### part a

We know that  $T \sim N(0, 1)$ . If a test rejects for large values of  $|T|$ , then this test rejects when  $T < -1.5$  and  $T > 1.5$ . Hence,

$$P(|T| > 1.5) = P(T < -1.5) + P(T > 1.5), \quad (14)$$

$$= \text{pnorm}(-1.5, 0, 1) + (1 - \text{pnorm}(1.5, 0, 1)) \quad (15)$$

$$= 0.1336. \quad (16)$$

### part b

Answer the same question if the test rejects for large  $T$ . That is,

$$P(T > 1.5) = 1 - \text{pnorm}(1.5, 0, 1) \quad (17)$$

$$= 0.0668. \quad (18)$$

## Exercise 2 - hints

### part a

1. Find the MLE for  $\theta$ . That's, find  $\hat{\theta} = ?$ ;

2. Find the  $\mathbb{E}(\hat{\theta})$  and  $\mathbb{V}(\hat{\theta}) = \text{CRLB}$ ;
3. Go back to page 10 (weeks 8 and 9, Confidence Interval) and that's it.

### **part b**

1. If  $Y = n\bar{X}/\theta \sim \chi^2_{2n}$ , we can define something like  $P(a < Y < b) = 0.95$ ;
2. Hence, we can try finding something like  $P(? < \theta < ??) = 0.95$ , if solve it for  $\theta$ ;
3. Finally, at  $n = 10$ , we can use the `qchisq(*, **)` (or a  $\chi^2$  table) to obtain the lower and upper limits of the CI for  $\theta$ .
